Dec. 21, 2007

Abstract

A library for reading and writing data in the SUSY Les Houches Accord 2 format is presented. The implementation is in native Fortran 77. The data are contained in a single array conveniently indexed by preprocessor statements.

1 Introduction

The original SUSY Les Houches Accord [1] (SLHA1 in the following) has standardized and significantly simplified the exchange of MSSM input and output parameters between such disparate applications as spectrum calculators and event generators. Meanwhile, agreement has been reached also about the encoding of many extensions of the MSSM which has led to a preliminary SLHA2 document [2].

While the SLHA specifications include the precise formats for Fortran I/O, it is nevertheless not entirely straightforward to read or write a file in SLHA format. The present library provides the user with simple routines to read and write files in SLHA format, as well as a few utility routines. One thing the library does not do is modify the numbers, which means there is no routine to compute, say, a particular quantity at a new scale. The data structures and subroutines are set up such that only very few changes are necessary when upgrading from the SLHALib 1 [3].

Sect. 2 describes the organization of the data structures, Sect. 3 gives the reference information for the library routines, Sect. 4 shows the usage in some examples, Sect. 5 contains download and build instructions, and Sect. 6 summarizes.

2 Data structures

The SLHA library is written in Fortran 77. All routines operate on a double complex array, `slhadata`, which is about the simplest conceivable data format for this purpose in Fortran. For convenience of use, this array is accessed via preprocessor statements, so the

user never needs to memorize any actual indices for the `slhadata` array. A file containing the preprocessor definitions must thus be included.

The `slhadata` array consists of a ‘static’ part containing the information from SLHA BLOCK sections and a ‘dynamic’ part containing the information from SLHA DECAY sections. The static part is indexed by preprocessor variables defined in `SLHA.h`, the dynamic part is accessed through the `SLHANewDecay`, `SLHAFindDecay`, `SLHAAddDecay`, `SLHAGetDecay`, and `SLHADecayTable` functions and subroutines (see Sect. 3).

In addition, descriptive names for the PDG codes of the particles are declared in `PDG.h`. These are needed e.g. to access the decay information.

2.1 SLHA blocks

The explicit indexing of the `slhadata` need not (and should not) be done by the user. Rather, the members of the SLHA data structure are accessed through preprocessor variables. Tables 1–11 list the preprocessor variables defined in `SLHA.h` which follow closely the definition of the Accord. Note that preprocessor symbols are case sensitive. On the downside, there is no way to guard against out-of-range indices, not even with compiler flags. This is because the preprocessor has no such checks and the compiler cannot determine *a posteriori* whether the single index it sees addresses the ‘right’ part of the array.

As far as there is overlap, the names for the block members have been chosen similar to the ones used in the MSSM model file of *FeynArts* [4]. Following is a list of common index conventions. This is only for a rough orientation: the actual indices and their ranges are always given explicitly in the Tables.

$t = 1 \dots 4$	(s)fermion type: 1 = (s)neutrinos, 2 = isospin-down (s)leptons, 3 = isospin-up (s)quarks, 4 = isospin-down (s)quarks
$g = 1 \dots 3$	(s)fermion generation
$s = 1 \dots 2$	number of sfermion mass-eigenstate, in the absence of mixing 1 = L, 2 = R
$c = 1 \dots 2$	number of chargino mass-eigenstate
$n = 1 \dots 4$	number of neutralino mass-eigenstate

For each block B the offset into `slhadata` and the length are respectively defined as `OffsetB` and `LengthB`. The contents of the block can be addressed through the macro `BlockB(i)`, where i runs from 1 to `LengthB`.

Matrices have a “Flat” array superimposed for convenience, in Fortran’s standard column-major convention, e.g. `USf(1,1) ≡ USfFlat(1)`, `USf(2,1) ≡ USfFlat(2)`, `USf(1,2) ≡ USfFlat(3)`, `USf(2,2) ≡ USfFlat(4)`. This makes it possible to e.g. copy such a matrix with just a single do-loop.

Table 12: The PDG codes defined in `PDG.h`.

2.2 PDG particle identifiers

`PDG.h` defines the human-readable versions of the PDG codes listed in Table 12. These are needed e.g. to access the decay information. At run time, the subroutine `SLHAPDGName` can be used to translate a PDG code into a particle name (see Sect. 3.12).

3 Routines provided by the SLHA library

The file `SLHA.h` must be included in every subroutine or function that uses SLHALib routines. It contains the necessary preprocessor definitions as well as external declarations for the SLHALib routines.

The basic data structure is the double complex array `slhadata` of length `nslhadata`. These names are hard-coded into the preprocessor definitions and may not be changed by the user. As a corollary, only one instance of the `slhadata` structure can be used in any one routine. This poses no serious limitation for most applications, however.

3.1 SLHAClear

```
subroutine SLHAClear(slhadata)
double complex slhadata(nslhadata)
```

This subroutine sets all data in the `slhadata` array given as argument to the value `invalid` (defined in `SLHA.h`). It is important that this is done before using `slhadata`, or else any kind of junk that happens to be in the memory occupied by `slhadata` will later on be interpreted as valid data.

3.2 SLHARead

```
subroutine SLHARead(error, slhadata, filename, abort)
integer error, abort
double complex slhadata(nslhadata)
character*(*) filename
```

This subroutine reads the data in SLHA format from `filename` into the `slhadata` array. If the specified file cannot be opened, the function issues an error message and returns `error = 1`. The `abort` flag governs what happens when superfluous text is read, i.e. text that cannot be interpreted as SLHA data. If `abort` is 0, a warning is printed and reading continues. Otherwise, reading stops at the offending line and `error = 2` is returned. `SLHARead` implicitly calls `SLHAClear` to clear the `slhadata` array before reading the file.

The blocks `SPINFO` and `DCINFO` are largely ignored when reading the file, as they are for human information only. Only the maximum of all message codes is kept in the `Severity` member of the block. Since the message codes increase with severity, this indicates the overall reliability of the corresponding data (spectrum or decay information). For example, if the `Severity` member is 4 (real errors), the Accord advises not to use the corresponding data. See also Sect. 3.4.

3.3 SLHAWrite

```
subroutine SLHAWrite(error, slhadata, filename)
integer error
double complex slhadata(nslhadata)
character*(*) filename
```

This subroutine writes the data in `slhadata` to `filename`.

3.4 SLHAInfo

```
subroutine SLHAInfo(slhablock, code, text)
double complex slhablock(*)
integer code
character*(*) text
```

This subroutine adds a message to one of the informational blocks, SPINFO or DCINFO. The block is most conveniently addressed through the `Block...` macros, for example

```
call SLHAInfo(BlockSPInfo(1), 4, "Error in computation")
```

Allowed codes are

- 1 = program name,
- 2 = program version,
- 3 = warning message,
- 4 = error message.

Messages are truncated at 80 characters.

3.5 SLHANewDecay

```
integer function SLHANewDecay(slhadata, width, parent_id)
double complex slhadata(nslhadata)
double precision width
integer parent_id
```

This function initiates the setting of decay information for the particle specified by the `parent_id` PDG code, whose total decay width is given by `width`. The return value is an integer index which is needed to subsequently add individual decay modes with `SLHAAddDecay`. If the fixed-length array `slhadata` becomes full, a warning is printed and zero is returned. If a decay of the given particle is already present in `slhadata`, it is first removed.

3.6 SLHAFindDecay

```
integer function SLHAFindDecay(slhadata, parent_id)
double complex slhadata(nslhadata)
integer parent_id
```

This function also initiates the setting of decay information. Unlike `SLHANewDecay`, it requires that the decay of the `parent_id` particle exist and reshuffles the decay information in `slhadata` such that new channels can be added to this decay. If no decay matching `parent_id` is found, the return value is 0, otherwise it is the index needed to add decay modes with `SLHAAddDecay`.

3.7 SLHAAddDecay

```
subroutine SLHAAddDecay(slhadata, br, decay,
&   nchildren, child1_id, child2_id, child3_id, child4_id)
double complex slhadata(nslhadata)
double precision br
integer decay
integer nchildren, child1_id, child2_id, child3_id, child4_id
```

This subroutine adds the decay mode

$$(\text{parent_id}) \rightarrow \text{child1_id} \text{ child2_id} \text{ child3_id} \text{ child4_id}$$

to the decay section previously initiated by `SLHANewDecay` or `SLHAFindDecay`. `decay` is the index obtained from the latter (which also set the `parent_id`) and `child n _id` are the PDG codes of the final-state particles. The branching ratio is given in `br`. If the fixed-length array `slhadata` becomes full, a warning is printed and `decay` is set to zero.

If `decay` is zero, an overflow of `slhadata` in an earlier invocation is silently assumed and no action is performed. It is therefore sufficient to check for overflow only once, after setting all decay modes (unless, of course, one needs to pinpoint the exact location of the overflow).

As with `SLHAGetDecay` (see Sect. 3.8), only the first `nchildren` of the `child n _id` are actually accessed and Fortran allows to omit the remaining ones in the invocation.

3.8 SLHAGetDecay

```
double precision function SLHAGetDecay(slhadata, parent_id,
&   nchildren, child1_id, child2_id, child3_id, child4_id)
double complex slhadata(*)
integer parent_id
integer nchildren, child1_id, child2_id, child3_id, child4_id
```

This function extracts the decay

$$\text{parent_id} \rightarrow \text{child1_id} \text{ child2_id} \text{ child3_id} \text{ child4_id}$$

from the `slhadata` array, or the value `invalid` (defined in `SLHA.h`) if no such decay can be found. The parent and child particles are given by their PDG identifiers (see Sect. 2.2). The return value is the total decay width if `nchildren = 0`, otherwise the branching ratio of the specified channel.

Note that only the first `nchildren` of the `childn_id` are actually accessed and Fortran allows to omit the remaining ones in the invocation (a strict syntax checker might issue a warning, though). Thus, for instance,

```
Zbb = SLHAGetDecay(slhadata, PDG_Z, 2, PDG_bottom, -PDG_bottom)
```

is a perfectly legitimate way to extract the $Z \rightarrow b\bar{b}$ decay.

3.9 SLHADecayTable

```
integer function SLHADecayTable(slhadata, parent_id,
&    width, id, maxparticles, maxchannels)
double complex slhadata(nslhadata)
integer parent_id, maxparticles, maxchannels
double precision width(maxchannels)
integer id(0:maxparticles,maxchannels)
```

This function stores all decay channels for the particle identified by `parent_id` in the arrays `id` and `width`. Unlike `SLHAGetDecay`, one does not need to know the exact decay mode in order to extract information. The value 0 for `parent_id` serves as a wildcard and transfers the entire decay table contained in `slhadata`. `SLHADecayTable` returns the number of channels found. The two arrays can be read out rather straightforwardly:

For each channel c ,

- $n = \text{id}(0, c)$ gives the number of participating particles, i.e. the number of decay products plus one.
- The PDG code of the decaying particle is in `id(1, c)`.
- The PDG codes of the decay products are in `id(2, c) ... id(n, c)`.
- If $n = 1$, `width(c)` contains the decaying particle's total width in GeV.
- If $n > 1$, `width(c)` contains the branching ratio for the given decay.

3.10 SLHAExist

```
integer function SLHAExist(slhablock, length)
double complex slhablock(*)
integer length
```

This function tests whether a given SLHA block is not entirely empty. It returns 2 if the block has at least one complex member, 1 if the block has at least one real member (i.e. all imaginary parts zero), and 0 if the block has no valid members at all. The SLHA blocks are most conveniently accessed using the `Block...` and `Length...` definitions (see Sect. 2), e.g.

```
if( SLHAExist(BlockMass(1), LengthMass) .ne. 0 ) ...
```

3.11 SLHAValid

```
integer function SLHAValid(slhablock, length)
double complex slhablock(*)
integer length
```

This function tests whether a given SLHA block consists entirely of valid data, i.e. it returns 0 if at least one member of the block is invalid. The SLHA blocks are most conveniently accessed using the `Block...` and `Length...` definitions (see Sect. 2), e.g.

```
if( SLHAValid(BlockNMix(1), LengthNMix) .ne. 0 ) ...
```

3.12 SLHAPDGName

```
subroutine SLHAPDGName(code, name)
integer code
character*(PDGLen) name
```

This subroutine translates a PDG code into a particle name. The sign of the PDG code is ignored, hence the same name is returned for a particle and its antiparticle. The maximum length of the name, `PDGLen`, is defined in `PDG.h`.

3.13 Incompatible Changes

Two incompatible changes in the interface were necessary with respect to the SLHALib 1 [3], largely due to the fact that the SLHA2 allows complex entries:

- `slhadata` is now a double complex, not a double precision array.

- The `SLHAExist` function has become an integer function, as it now distinguishes *three* possible scenarios: no valid entries, only real entries, and complex entries.
- The `SLHAWrite` subroutine no longer has arguments for program name and version. Such informational messages can now be added with the much more general subroutine `SLHAInfo`.

4 Examples

Consider the following example program, which just copies one SLHA file to another:

```

program copy_slha_file
  implicit none

#include "SLHA.h"

  integer error
  double complex slhadata(nslhadata)

  call SLHARead(error, slhadata, "infile.slha", 0)
  if( error .ne. 0 ) stop "Read error"

  call SLHAInfo(BlockSPInfo(1), 1, "My Test Program")
  call SLHAInfo(BlockSPInfo(1), 2, "1.0")

  call SLHAWrite(error, slhadata, "outfile.slha")
  if( error .ne. 0 ) stop "Write error"
end

```

Already in this simple program a couple of things can be seen:

- the file `SLHA.h` must be included in every function or subroutine that uses the SLHA routines and this must be done using the preprocessor `#include` (not Fortran's `include`), thus the program file should have the extension `.F` (capital F).
- `slhadata` must be declared as a double complex array of length `nslhadata`.
- One should not continue with processing if a non-zero error flag is returned.

A more sensible application would add something to the `slhadata` before writing them out again. The next little program pretends to compute the fermionic Z decays (by calling a hypothetical subroutine `MyCalculation`) and adds them to `slhadata`:

```

        program compute_decays
        implicit none

#include "SLHA.h"
#include "PDG.h"

        integer error, decay, t, g
        double complex slhadata(nslhadata)
        double precision total_width, br(4,3)
        integer ferm_id(4,3)
        data ferm_id /
&    PDG_nu_e, PDG_electron, PDG_up, PDG_down,
&    PDG_nu_mu, PDG_muon, PDG_charm, PDG_strange,
&    PDG_nu_tau, PDG_tau, PDG_top, PDG_bottom /

        call SLHARead(error, slhadata, "infile.slha", 0)
        if( error .ne. 0 ) stop "Read error"

* compute the decays with parameters taken from the slhadata:
        call MyCalculation(SMInputs_MZ, MinPar_TB, ...,
&    total_width, br)

        decay = SLHANewDecay(slhadata, total_width, PDG_Z)
        do g = 1, 3
            do t = 1, 4
                call SLHAAddDecay(slhadata, br(t,g), decay,
&    2, ferm_id(t,g), -ferm_id(t,g))
            enddo
        enddo

        call SLHAInfo(BlockDCInfo(1), 1, "My Decay Calculator")
        call SLHAInfo(BlockDCInfo(1), 2, "3.1415")

        call SLHAWrite(error, slhadata, "outfile.slha")
        if( error .ne. 0 ) stop "Write error"
        end

```

Demonstrated here is the access of SLHA data (SMInputs_MZ, MinPar_TB) and the setting of decay information.

5 Building and Compiling

The SLHA library package can be downloaded as a gzipped tar archive from the Web site <http://www.feynarts.de/slha>. After unpacking the archive, change into the directory SLHALib-2.1 and type

```
./configure
make
make install
```

Some simple demonstration programs are located in the `demo` subdirectory.

Compiling a program that uses the SLHA library is in principle equally straightforward. The only tricky thing is that one has to relax Fortran's 72-column limit. This is because even lines perfectly within the 72-column range may become longer after the preprocessor's substitutions. While essentially every Fortran compiler offers such an option, the name is quite different. A glance at the man page should suffice to find out. Here are a few common choices:

Compiler	Platform/OS	Option name
g77	any	<code>-ffixed-line-length-none</code>
pgf77	Linux x86	<code>-Mextend</code>
ifort	Linux x86	<code>-extend_source</code>
f77	Tru64 Alpha	<code>-extend_source</code>
f77	SunOS, Solaris	<code>-e</code>
fort77	HP-UX	<code>+es</code>

To compile and link your program, add this option and `-Ipath -Lpath -lSLHA` to the compiler command line, where *path* is the location of the SLHA library, e.g.

```
SLHALIB=$HOME/SLHALib-2.1/$HOSTTYPE
pgf77 -Mextend -I$SLHALIB/include myprogram.F -L$SLHALIB/lib -lSLHA
```

All externally visible symbols of the SLHA library start with the prefix `SLHA` and should thus pretty much avoid symbol conflicts.

It is also possible to use the SLHALib in C and C++. In this case one needs to include the header file `CSLHA.h` in the program text. Compilation should be done using the `fcc` script, i.e. replace the invocation of the C compiler with `fcc`, as in

```
fcc -I$SLHALIB/include myprogram.c -L$SLHALIB/lib -lSLHA
```

The `fcc` script is installed together with the library and automatically adds the necessary libraries for linking with Fortran code.

6 Summary

The SLHA library presented here provides simple functions to read and write files in SLHA format. Data are kept in a single double complex array and accessed through preprocessor variables. The library is written in native Fortran 77 and is easy to build. The source code is openly available at <http://www.feynarts.de/slha> and is distributed under the GNU Library General Public License.

The author welcomes any kind of feedback, in particular bug and performance reports, at hahn@feynarts.de.

Acknowledgements

I thank J. Guasch for providing a first implementation of some SLHA2 features and introducing useful routines.
